I will analyze scenario B, which says:

- A hospital chatbot stores patient questions to improve its AI model.

1. What data is collected?
   The chatbot collects patients' questions.

2. Why is the data collected?
   The data is collected to improve chatbot's AI model.

3. Is it necessary?
   Collecting patients' questions might improve chatbot's ability to answer their questions in future. However, collecting their personal information that found in questions isn't necessary. The chatbot should only collect the questions and avoid collecting patient's personal data.

4. Is the user informed?
   Patients should be clearly informed how data they are just entering will be collected and used. The chatbot should ensure they are aware about that before it starts collecting and using their data.

5. What harms are possible?
   There is a lot of possible harm in that case. One of them is database leak. If the chatbot's database have been hacked, patients' data might be leaked, leading to patients' privacy violation. Another possible harm is the annoying advertisements. Patients' might get spam of advertisements just because they asked that chatbot, which means the chatbot's collected data has been shared to third parties.

6. What safeguards are needed?
   The chatbot's database should use a strict security systems to prevent any possible cyberattacks targeting patients' information. Consent is another important criteria, once patients' start to be careful what they are sending to the chatbot, even if the database has been leaked the patients' wouldn't get any harm. Also, the chatbot shouldn't collect but question-related information. That way the patients' privacy will be safe from any harm.

Conclusion: The chatbot should ensure that patients' know what data will be collected from their messages and how it will be used by informing them. Another thing is that patients should be aware they shouldn't include any personal data in their questions to the chatbot. Also, the chatbot's database should be secure through strong measurements of security.
